Factor Graphs and message passing

Carl Edward Rasmussen

October 28th, 2016

Key concepts

- · Factor graphs are a class of graphical model
- A factor graph represents the product structure of a function, and contains factor nodes and variable nodes
- We can compute marginals and conditionals efficiently by passing messages on the factor graph, this is called the sum-product algorithm (a.k.a. belief propagation or factor-graph propagation)
- We can apply this to the True Skill graph
- But certain messages need to be approximated
- One approximation method based on <u>moment matching</u> is called Expectation Propagation (EP)

Factor Graphs

Factor graphs are a type of *probabilistic graphical model* (others are directed graphs, a.k.a. Bayesian networks, and undirected graphs, a.k.a. Markov networks).

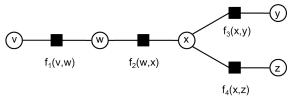

Factor graphs allow to represent the product structure of a function.

Example: consider the factorising probability distribution:

$$p(v, w, x, y, z) = f_1(v, w)f_2(w, x)f_3(x, y)f_4(x, z)$$

A factor graph is a bipartite graph with two types of nodes:

- Factor node: Variable node: ○
- Edges represent the dependency of factors on variables.

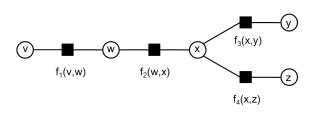

Factor Graphs

- What are the marginal distributions of the individual variables?
- What is p(w)?
- How do we compute conditional distributions, e.g. p(w|y)?

For now, we will focus on tree-structured factor graphs.

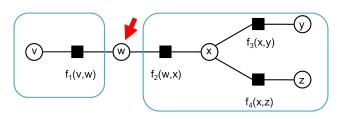

Factor trees: separation (1)

$$p(w) = \sum_{v} \sum_{x} \sum_{y} \sum_{z} f_1(v, w) f_2(w, x) f_3(x, y) f_4(x, z)$$

- If w, v, x, y and z take K values each, we have $\approx 3K^4$ products and $\approx K^4$ sums, for each value of w, i.e. total $O(K^5)$.
- Multiplication is distributive: ca + cb = c(a + b). The right hand side is more efficient! 3 operations vs. 2 operations.

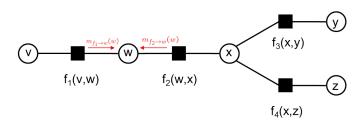

Factor trees: separation (2)

$$\begin{array}{lcl} p(w) & = & \displaystyle \sum_{\nu} \sum_{x} \sum_{y} \sum_{z} f_{1}(\nu, w) f_{2}(w, x) f_{3}(x, y) f_{4}(x, z) \\ \\ & = & \displaystyle \left[\sum_{\nu} f_{1}(\nu, w) \right] \cdot \left[\sum_{x} \sum_{y} \sum_{z} f_{2}(w, x) f_{3}(x, y) f_{4}(x, z) \right] \\ \\ & & \qquad \qquad O(K^{2}) \quad O(1) & O(K^{4}) \end{array}$$

- In a tree, each node separates the graph into disjoint parts.
- Grouping terms, we go from sums of products to products of sums.
- The complexity is now $\mathcal{O}(K^4)$.

Factor trees: separation (3)

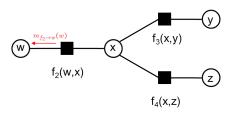

$$p(w) = \underbrace{\left[\sum_{v} f_1(v, w)\right]}_{m_{f_1 \to w}(w)} \cdot \underbrace{\left[\sum_{x} \sum_{y} \sum_{z} f_2(w, x) f_3(x, y) f_4(x, z)\right]}_{m_{f_2 \to w}(w)}$$

• Sums of products becomes <u>products of sums</u> of all messages from neighbouring factors to variable.

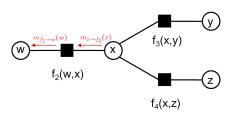

w

Messages: from factors to variables (1)

$$\mathbf{m}_{\mathbf{f}_2 \to \mathbf{w}}(\mathbf{w}) = \sum_{\mathbf{x}} \sum_{\mathbf{y}} \sum_{\mathbf{z}} f_2(\mathbf{w}, \mathbf{x}) f_3(\mathbf{x}, \mathbf{y}) f_4(\mathbf{x}, \mathbf{z})$$

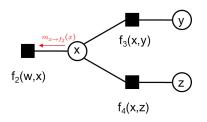

Messages: from factors to variables (2)

$$\begin{array}{ll} \mathbf{m}_{\mathbf{f}_2 \to \mathbf{w}}(\mathbf{w}) & = & \displaystyle \sum_{\mathbf{x}} \sum_{\mathbf{y}} \sum_{\mathbf{z}} f_2(\mathbf{w}, \mathbf{x}) f_3(\mathbf{x}, \mathbf{y}) f_4(\mathbf{x}, \mathbf{z}) \\ \\ & = & \displaystyle \sum_{\mathbf{x}} f_2(\mathbf{w}, \mathbf{x}) \cdot \left[\sum_{\mathbf{y}} \sum_{\mathbf{z}} f_3(\mathbf{x}, \mathbf{y}) f_4(\mathbf{x}, \mathbf{z}) \right] \\ \\ & \underbrace{\mathbf{m}_{\mathbf{x} \to \mathbf{f}_2}(\mathbf{x})} \end{array}$$

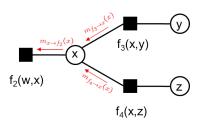

• Factors only need to sum out all their local variables.

Messages: from variables to factors (1)

$$m_{x \to f_2}(x) = \sum_{y} \sum_{z} f_3(x, y) f_4(x, z)$$

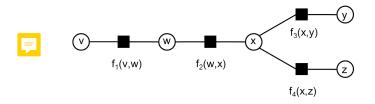

Messages: from variables to factors (2)

$$\begin{array}{lcl} \mathbf{m}_{\mathbf{x} \to \mathbf{f}_2}(\mathbf{x}) & = & \displaystyle \sum_{\mathbf{y}} \sum_{\mathbf{z}} \mathbf{f}_3(\mathbf{x}, \mathbf{y}) \mathbf{f}_4(\mathbf{x}, \mathbf{z}) \\ \\ & = & \displaystyle \left[\sum_{\mathbf{y}} \mathbf{f}_3(\mathbf{x}, \mathbf{y}) \right] \cdot \underbrace{\left[\sum_{\mathbf{z}} \mathbf{f}_4(\mathbf{x}, \mathbf{z}) \right]}_{\mathbf{m}_{\mathbf{f}_3 \to \mathbf{x}}(\mathbf{x})} \end{array}$$

• Variables pass on the product of all incoming messages.

Factor graph marginalisation: summary

$$\begin{split} p(w) &= \sum_{\nu} \sum_{x} \sum_{y} \sum_{z} f_{1}(\nu, w) f_{2}(w, x) f_{3}(x, y) f_{4}(x, z) \\ &= \underbrace{\left[\sum_{\nu} f_{1}(\nu, w)\right] \cdot \left[\sum_{x} f_{2}(w, x) \cdot \left[\left[\sum_{y} f_{3}(x, y)\right] \cdot \left[\sum_{z} f_{4}(x, z)\right]\right]\right]}_{\mathfrak{m}_{f_{3} \to x}(x)} \underbrace{\left[\sum_{y} f_{3}(x, y)\right] \cdot \left[\sum_{x} f_{4}(x, z)\right]\right]}_{\mathfrak{m}_{f_{3} \to x}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{4} \to x}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]\right]}_{\mathfrak{m}_{f_{3} \to x}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{4} \to x}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]\right]}_{\mathfrak{m}_{f_{2} \to w}(w)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x} f_{4}(x, x)\right]}_{\mathfrak{m}_{f_{2} \to w}(x)} \underbrace{\left[\sum_{x$$

• The complexity is reduced from $\mathcal{O}(K^5)$ (naïve implementation) to $\mathcal{O}(K^2)$.

The sum-product algorithm

In summary, message passing involved three update equations:

Marginals are the product of all incoming messages from neighbour factors

$$p(t) = \prod_{f \in F_t} m_{f \to t}(t)$$

Messages from factors sum out all variables except the receiving one

$$m_{f \rightarrow t_1}(t_1) = \sum_{t_2} \sum_{t_3} \ldots \sum_{t_n} f(t_1, t_2, \ldots, t_n) \prod_{i \neq 1} m_{t_i \rightarrow f}(t_i)$$

Messages from variables are the product of all incoming messages except the message from the receiving factor

$$m_{t \rightarrow f}(t) = \prod_{f_j \in F_t \setminus \{f\}} m_{f_j \rightarrow t}(t) = \frac{p(t)}{m_{f \rightarrow t}(t)}$$

Messages are results of partial computations. Computations are localised.
